

What is e?

Dennis Chen

2020

Familiarity with basic calculus, including Taylor Series, is assumed. If you've never done calculus before, please read [Differentiation – In a Nutshell](#).

We start by defining what e is.

e. The constant e is defined such that the derivative of $f(x) = e^x$ at $x = 0$ is 1.

This is the entire definition of e – **any other results follow from this definition**.¹ Obviously, e is unique and exists since the derivative increases continuously as x increases.²

Now we want to show that the derivative of e^x is e^x in general. Fortunately, this is very easy with the limit definition of the derivative.

Derivative of e^x . The derivative of $f(x) = e^x$ is e^x .

Proof. By the limit definition of the derivative,

$$f'(x) = \lim_{\Delta x \rightarrow 0} \frac{e^{x+\Delta x} - e^x}{\Delta x} = e^x \lim_{\Delta x \rightarrow 0} \frac{e^{\Delta x} - 1}{\Delta x} = e^x \cdot 1,$$

where the last equation follows by the definition of e .

That's all fine and well, but now we have to show that the only function that satisfies $f'(x) = f(x)$ is e^x .³

$f'(x) = f(x)$. The only functions that satisfy $f'(x) = f(x)$ are of the form $k \cdot e^x$.

¹You can define it the other way around and work backwards, but I am of the opinion that this is the most natural and convenient definition.

²Here is a short proof that this is actually true: Note that the derivative of $f(x) = k^x$ is $\lim_{\Delta x \rightarrow 0} \frac{k^{x+\Delta x} - k^x}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{k^{x \ln k} (k^{\Delta x \ln k} - 1)}{\Delta x} = k^{x \ln k} \ln k = \ell k$, where ℓ is the derivative of e^x at 0. The base of e is actually arbitrary; it doesn't matter. You can replace it with 10 or whatever you want.

³This actually isn't exactly true because of addition and scalar multiplication, but bear with me for a moment.

Proof. Note that the Maclaurin Series of $f(x)$ can be expressed as

$$f(x) = \frac{f(0)}{0!} + \frac{f'(0)x}{1!} + \frac{f''(0)x^2}{2!} + \dots.$$

Since $f'(x) = f(x)$, then $f^{(n)}(0) = f(0)$, we can express the sum as

$$f(x) = f(0)\left(\frac{1}{0!} + \frac{x}{1!} + \frac{x^2}{2!} + \dots\right) = f(0)e^x.$$

Now we have to show that this is actually the Maclaurin Series. Fortunately, this is the easy part; we just proved that there is exactly one function with $f(0) = 1$ that satisfies $f'(x) = f(x)$, and we proved before that e^x also satisfies this.^a So the Maclaurin Series with $f(0) = 1$ could only represent $f(x) = e^x$, and $f(0)$ just accounts for the constant factor k .

^aYou technically have to still show $e^0 = 1$, but that's just a trivial detail.

A corollary of this is the following definition of e .

e as a sum. The constant e is defined as

$$\frac{1}{0!} + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \dots.$$

One final thing you should know about e .

e as a limit. The constant e is equal to the value $\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n$.

Proof. Note that expanding gives us

$$\lim_{n \rightarrow \infty} \sum_{i=0}^n \left(\frac{1}{n}\right)^i \binom{n}{i}.$$

Since n approaches infinity, we only need to care about two things: the constant factor and the order. Therefore, this sum is equal to

$$\lim_{n \rightarrow \infty} \sum_{i=0}^n \left(\frac{1}{n}\right)^i \frac{n!}{(n-i)!i!} \sim \lim_{n \rightarrow \infty} \sum_{i=0}^n \left(\frac{1}{n}\right)^i \frac{n^i}{i!} = \lim_{n \rightarrow \infty} \sum_{i=0}^n \frac{1}{i!} = e.$$

Exercise. Find the value of $\lim_{n \rightarrow \infty} \left(1 + \frac{1}{2n}\right)^{3n}$.
